SAMPLING FRESHLY MIXED CONCRETE
WAQTC TM 2

Following are guidelines for the use of WAQTC FOP for WAQTC TM 2 (Concrete 9-1 (14), published October 2017) by the State of Alaska DOT&PF.

I. Under Apparatus, Apparatus for wet sieving, add the following clarification:
   Mixes with aggregates larger than 1.5 inch require apparatus for wet sieving, including: a sieve(s), conforming to AASHTO M 92 (ASTM E11), minimum of 2 ft² (0.19 m²) of sieving area, 1.5 inch screen openings, and conveniently arranged and supported so that the sieve can be shaken rapidly by hand.
This page intentionally left blank.
SAMPLING FRESHLY MIXED CONCRETE
FOP FOR WAQTC TM 2

Scope
This method covers procedures for obtaining representative samples of fresh concrete delivered to the project site. The method includes sampling from stationary, paving and truck mixers, and from agitating and non-agitating equipment used to transport central mixed concrete.

This method also covers the removal of large aggregate particles by wet sieving.

Sampling concrete may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices.

Warning—Fresh Hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.

Apparatus
- Wheelbarrow
- Cover for wheelbarrow (plastic, canvas, or burlap)
- Buckets
- Shovel
- Cleaning equipment, including scrub brush, rubber gloves, water
- Apparatus for wet sieving, including: a sieve(s), meeting the requirements of FOP for AASHTO T 27/T 11, minimum of 2 ft² (0.19 m²) of sieving area, conveniently arranged and supported so that the sieve can be shaken rapidly by hand.

Procedure
1. Use every precaution in order to obtain samples representative of the true nature and condition of the concrete being placed being careful not to obtain samples from the very first or very last portions of the batch. The size of the sample will be 1.5 times the volume of concrete required for the specified testing, but not less than 0.03 m³ (1 ft³).

2. Dampen the surface of the receptacle just before sampling, empty any excess water.

Note 1: Sampling should normally be performed as the concrete is delivered from the mixer to the conveying vehicle used to transport the concrete to the forms; however, specifications may require other points of sampling, such as at the discharge of a concrete pump.
3. Use one of the following methods to obtain the sample:

- **Sampling from stationary mixers**
  Obtain the sample after a minimum of 1/2 m³ (1/2 yd³) of concrete has been discharged. Perform sampling by passing a receptacle completely through the discharge stream, or by completely diverting the discharge into a sample container. Take care not to restrict the flow of concrete from the mixer, container, or transportation unit so as to cause segregation. These requirements apply to both tilting and nontilting mixers.

- **Sampling from paving mixers**
  Obtain the sample after the contents of the paving mixer have been discharged. Obtain material from at least five different locations in the pile and combine into one test sample. Avoid contamination with subgrade material or prolonged contact with absorptive subgrade. To preclude contamination or absorption by the subgrade, the concrete may be sampled by placing a shallow container on the subgrade and discharging the concrete across the container.

- **Sampling from revolving drum truck mixers or agitators**
  Obtain the sample after a minimum of 1/2 m³ (1/2 yd³) of concrete has been discharged. Obtain samples after all of the water has been added to the mixer. Do not obtain samples from the very first or last portions of the batch discharge. Perform sampling by repeatedly passing a receptacle through the entire discharge stream or by completely diverting the discharge into a sample container. Regulate the rate of discharge of the batch by the rate of revolution of the drum and not by the size of the gate opening.

- **Sampling from open-top truck mixers, agitators, non-agitating equipment or other types of open-top containers**
  Obtain the sample by whichever of the procedures described above is most applicable under the given conditions.

- **Sampling from pump or conveyor placement systems**
  Obtain sample after a minimum of 1/2 m³ (1/2 yd³) of concrete has been discharged. Obtain samples after all of the pump slurry has been eliminated. Perform sampling by repeatedly passing a receptacle through the entire discharge system or by completely diverting the discharge into a sample container. Do not lower the pump arm from the placement position to ground level for ease of sampling, as it may modify the air content of the concrete being sampled. Do not obtain samples from the very first or last portions of the batch discharge.

4. Transport samples to the place where fresh concrete tests are to be performed and specimens are to be molded. They shall then be combined and remixed with a shovel the minimum amount necessary to ensure uniformity. Protect the sample from direct sunlight, wind, rain, and sources of contamination.

5. Complete test for temperature and start tests for slump and air content within 5 minutes of obtaining the sample. Start molding specimens for strength tests within 15 minutes of obtaining the sample. Complete the test methods as expeditiously as possible.
Wet Sieving

When required due to oversize aggregate, the concrete sample shall be wet sieved, after transporting but prior to remixing, for slump testing, air content testing or molding test specimens, by the following:

1. Place the sieve designated by the test procedure over the dampened sample container.
2. Pass the concrete over the designated sieve. Do not overload the sieve (one particle thick).
3. Shake or vibrate the sieve until no more material passes the sieve. A horizontal back and forth motion is preferred.
4. Discard oversize material including all adherent mortar.
5. Repeat until sample of sufficient size is obtained. Mortar adhering to the wet-sieving equipment shall be included with the sample.
6. Using a shovel, remix the sample the minimum amount necessary to ensure uniformity.

*Note 2:* Wet sieving is not allowed for samples being used for density determinations according to the FOP for AASHTO T 121.

ATM 502  Temperature of Freshly Mixed Portland Cement Concrete

TEMPERATURE OF FRESHLY MIXED PORTLAND CEMENT CONCRETE
WAQTC FOP FOR AASHTO T 309

Following are guidelines for the use of WAQTC FOP for AASHTO T 309 (Concrete 10-1 (15), published October 2017) by the State of Alaska DOT&PF.
This page intentionally left blank.
TEMPERATURE OF FRESHLY MIXED PORTLAND CEMENT CONCRETE
FOP FOR AASHTO T 309

Scope
This procedure covers the determination of the temperature of freshly mixed Portland Cement Concrete in accordance with AASHTO T 309-15.

Warning—Fresh Hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.

Apparatus
- Container — The container shall be made of non-absorptive material and large enough to provide at least 75 mm (3 in.) of concrete in all directions around the sensor; concrete cover must also be at least three times the nominal maximum size of the coarse aggregate.
- Temperature measuring device — The temperature measuring device shall be calibrated and capable of measuring the temperature of the freshly mixed concrete to ±0.5°C (±1°F) throughout the temperature range likely to be encountered. Partial immersion liquid-in-glass thermometers (and possibly other types) shall have a permanent mark to which the device must be immersed without applying a correction factor.
- Reference temperature measuring device — The reference temperature measuring device shall be a thermometric device readable to 0.2°C (0.5°F) that has been verified and calibrated. The calibration certificate or report indicating conformance to the requirements of ASTM E 77 shall be available for inspection.

Calibration of Temperature Measuring Device
Each temperature measuring device shall be verified for accuracy annually and whenever there is a question of accuracy. Calibration shall be performed by comparing readings on the temperature measuring device with another calibrated instrument at two temperatures at least 15°C or 27°F apart.

Sample Locations and Times
The temperature of freshly mixed concrete may be measured in the transporting equipment, in forms, or in sample containers, provided the sensor of the temperature measuring device has at least 75 mm (3 in.) of concrete cover in all direction around it.

Complete the temperature measurement of the freshly mixed concrete within 5 minutes of obtaining the sample.

Concrete containing aggregate of a nominal maximum size greater than 75 mm (3 in.) may require up to 20 minutes for the transfer of heat from the aggregate to the mortar after batching.

Procedure
1. Dampen the sample container.
2. Obtain the sample in accordance with the FOP for WAQTC TM 2.
3. Place sensor of the temperature measuring device in the freshly mixed concrete so that it has at least 75 mm (3 in.) of concrete cover in all directions around it.

4. Gently press the concrete in around the sensor of the temperature measuring device at the surface of the concrete so that air cannot reach the sensor.

5. Leave the sensor of the temperature measuring device in the freshly mixed concrete for a minimum of two minutes, or until the temperature reading stabilizes.

6. Complete the temperature measurement of the freshly mixed concrete within 5 minutes of obtaining the sample.

7. Read and record the temperature to the nearest 0.5°C (1°F).

**Report**
- Results on forms approved by the agency
- **Sample ID**
- Measured temperature of the freshly mixed concrete to the nearest 0.5°C (1°F)

ATM 503  Slump of Hydraulic Cement Concrete

SLUMP OF HYDRAULIC CEMENT CONCRETE
WAQTC FOP FOR AASHTO T 119

Following are guidelines for the use of WAQTC FOP for AASHTO T 119 (Concrete 11-1 (16), published October 2017) by the State of Alaska DOT&PF.
This page intentionally left blank.
SLUMP OF HYDRAULIC CEMENT CONCRETE
FOP FOR AASHTO T 119

Scope
This procedure provides instructions for determining the slump of hydraulic cement concrete in accordance with AASHTO T 119-13. It is not applicable to non-plastic and non-cohesive concrete.

Warning—Fresh Hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.

Apparatus
- Mold: A metal frustum of a cone provided with foot pieces and handles. The mold must be constructed without a seam. The interior of the mold shall be relatively smooth and free from projections such as protruding rivets. The mold shall be free from dents. A mold that clamps to a rigid nonabsorbent base plate is acceptable provided the clamping arrangement is such that it can be fully released without movement of the mold.
- Mold: If other than metal, it must conform to AASHTO T 119, Sections 5.1.2.1 and 5.1.2.2.
- Tamping rod: 16 mm (5/8 in.) diameter and 400 mm (16 in.) to 600 mm (24 in.) long, having a hemispherical tip the same diameter as the rod. (Hemispherical means “half a sphere”; the tip is rounded like half of a ball.)
- Scoop: a receptacle of appropriate size so that each representative increment of the concrete sample can be placed in the container without spillage.
- Tape measure or ruler with at least 5 mm or 1/8 in. graduations
- Base: Flat, rigid, non-absorbent moistened surface on which to set the slump mold

Procedure
1. Obtain the sample in accordance with the FOP for WAQTC TM 2. If the concrete mixture contains aggregate retained on the 37.5mm (1½ in.) sieve, the aggregate must be removed in accordance with the Wet Sieving portion of the FOP for WAQTC TM 2.
   
   Note 1: Testing shall begin within five minutes of obtaining the sample.
2. Dampen the inside of the mold and place it on a dampened, rigid, nonabsorbent surface that is level and firm.
3. Stand on both foot pieces in order to hold the mold firmly in place.
4. Use the scoop to fill the mold 1/3 full by volume, to a depth of approximately 67 mm (2 5/8 in.) by depth.
5. Consolidate the layer with 25 strokes of the tamping rod, using the rounded end. Distribute the strokes evenly over the entire cross section of the concrete.
For this bottom layer, incline the rod slightly and make approximately half the strokes near the perimeter, and then progress with vertical strokes, spiraling toward the center.

6. Use the scoop to fill the mold 2/3 full by volume, to a depth of approximately 155 mm (6 1/8 in.) by depth.

7. Consolidate this layer with 25 strokes of the tamping rod, penetrate approximately 25 mm (1 in.) into the bottom layer. Distribute the strokes evenly.

8. Use the scoop to fill the mold to overflowing.

9. Consolidate this layer with 25 strokes of the tamping rod, penetrate approximately 25 mm (1 in.) into the second layer. Distribute the strokes evenly. If the concrete falls below the top of the mold, stop, add more concrete, and continue rodding for a total of 25 strokes. Keep an excess of concrete above the top of the mold at all times. Distribute strokes evenly as before.

10. Strike off the top surface of concrete with a screeding and rolling motion of the tamping rod.

11. Clean overflow concrete away from the base of the mold.

12. Remove the mold from the concrete by raising it carefully in a vertical direction. Raise the mold 300 mm (12 in.) in 5 ±2 seconds by a steady upward lift with no lateral or torsional (twisting) motion being imparted to the concrete.

   The entire operation from the start of the filling through removal of the mold shall be carried out without interruption and shall be completed within an elapsed time of 2 1/2 minutes. Immediately measure the slump.

13. Invert the slump mold and set it next to the specimen.

14. Lay the tamping rod across the mold so that it is over the test specimen.

15. Measure the distance between the bottom of the rod and the displaced original center of the top of the specimen to the nearest 5 mm (1/4 in.).

   Note 2: If a decided falling away or shearing off of concrete from one side or portion of the mass occurs, disregard the test and make a new test on another portion of the sample. If two consecutive tests on a sample of concrete show a falling away or shearing off of a portion of the concrete from the mass of the specimen, the concrete probably lacks the plasticity and cohesiveness necessary for the slump test to be applicable.

16. Discard the tested sample.

Report

- Results on forms approved by the agency
- Sample ID
- Slump to the nearest 5 mm (1/4 in.).
ATM 504  Density (Unit Weight), Yield, and Air Content (Gravimetric) of Concrete

Following are guidelines for the use of WAQTC FOP for AASHTO T 121 (Concrete 12-1 (17), published October 2017) by the State of Alaska DOT&PF.

1. Under the Heading of Procedure – Rodding, delete “dry” from step 2 then reverse steps 2 and 3.
2. Report the volume of the measure to 0.000001 m³ (0.0001 ft³).
3. Calculate aggregate free water mass as follows (use decimal form):

   Free Water Mass = Total Aggregate Mass − Aggregate SSD Mass

   \[
   \text{Aggregate SSD Mass} = \frac{\text{Total Aggregate Mass}}{1 + (\text{Aggregate Moisture Content})} \times (1 + \text{Percent Absorption})
   \]

4. Free water percentage = Total moisture content of aggregate − absorbed moisture
This page intentionally left blank.
DENSITY (UNIT WEIGHT), YIELD, AND AIR CONTENT (GRAVIMETRIC) OF CONCRETE FOP FOR AASHTO T 121

Scope

This procedure covers the determination of density, or unit weight, of freshly mixed concrete in accordance with AASHTO T 121-17. It also provides formulas for calculating the volume of concrete produced from a mixture of known quantities of component materials, and provides a method for calculating cement content and cementitious material content – the mass of cement or cementitious material per unit volume of concrete. A procedure for calculating water/cement ratio is also covered.

Warning—Fresh Hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.

Apparatus

- Measure: May be the bowl portion of the air meter used for determining air content under the FOP for AASHTO T 152. Otherwise, it shall be a metal cylindrical container meeting the requirements of AASHTO T 121. The capacity and dimensions of the measure shall conform to those specified in Table 1.

- Balance or scale: Accurate to within 45 g (0.1 lb) or 0.3 percent of the test load, whichever is greater, at any point within the range of use.

- Tamping rod: 16 mm (5/8 in.) diameter and 400 mm (16 in.) to 600 mm (24 in.) long, having a hemispherical tip the same diameter as the rod. (Hemispherical means “half a sphere”; the tip is rounded like half of a ball.)

- Vibrator: 7000 vibrations per minute, 19 to 38 mm (3/4 to 1 1/2 in.) in diameter, and the length of the shaft shall be at least 610 mm (24 in.).

- Scoop: a receptacle of appropriate size so that each representative increment of the concrete sample can be placed in the container without spillage.

- Strike-off plate: A flat rectangular metal plate at least 6 mm (1/4 in.) thick or a glass or acrylic plate at least 12 mm (1/2 in.) thick, with a length and width at least 50 mm (2 in.) greater than the diameter of the measure with which it is to be used. The edges of the plate shall be straight and smooth within tolerance of 1.5 mm (1/16 in.).

- Mallet: With a rubber or rawhide head having a mass of 0.57 ±0.23 kg (1.25 ±0.5 lb) for use with measures of 0.014 m³ (1/2 ft³) or less, or having a mass of 1.02 ±0.23 kg (2.25 ±0.5 lb) for use with measures of 0.028 m³ (1 ft³).

* Note: The indicated size of measure shall be for aggregates of nominal maximum size equal to or smaller than that listed.

** Measure may be the base of the air meter used in the FOP for AASHTO T 152.

*** Nominal maximum size: One sieve larger than the first sieve to retain more than 10 percent of the material using an agency specified set of sieves based on cumulative percent retained. Where large gaps in specification sieves exist, intermediate sieve(s) may be inserted to determine nominal maximum size.

Procedure Selection

There are two methods of consolidating the concrete – rodding and vibration. If the slump is greater than 75 mm (3 in.), consolidation is by rodding. When the slump is 25 to 75 mm (1 to 3 in.), internal vibration or rodding can be used to consolidate the sample, but the method used must be that required by the agency in order to obtain consistent, comparable results. For concrete with slump less than 25 mm (1 in.), consolidate the sample by internal vibration. Do not consolidate self-consolidating concrete (SCC).

When using measures greater than 0.0142 m³ (1/2 ft³) see AASHTO T 121.

Procedure – Rodding

1. Obtain the sample in accordance with the FOP for WAQTC TM 2. Testing may be performed in conjunction with the FOP for AASHTO T 152. When doing so, this FOP should be performed prior to the FOP for AASHTO T 152.

   **Note 1:** If the two tests are being performed using the same sample, this test shall begin within five minutes of obtaining the sample.

2. Determine the mass of the dry empty measure.

3. Dampen the inside of the measure.

4. Use the scoop to fill the measure approximately 1/3 full with concrete. Evenly distribute the concrete in a circular motion around the inner perimeter of the measure.

5. Consolidate the layer with 25 strokes of the tamping rod, using the rounded end. Distribute the strokes evenly over the entire cross section of the concrete. Rod throughout its depth without hitting the bottom too hard.
6. Tap around the perimeter of the measure smartly 10 to 15 times with the mallet to close voids and release trapped air.

7. Add the second layer, filling the measure about 2/3 full. Evenly distribute the concrete in a circular motion around the inner perimeter of the measure.

8. Consolidate this layer with 25 strokes of the tamping rod, penetrating about 25 mm (1 in.) into the bottom layer.

9. Tap around the perimeter of the measure smartly 10 to 15 times with the mallet.

10. Add the final layer, slightly overfilling the measure. Evenly distribute the concrete in a circular motion around the inner perimeter of the measure.

11. Consolidate this layer with 25 strokes of the tamping rod, penetrating about 25 mm (1 in.) into the second layer.

12. Tap **around the perimeter** of the measure smartly 10 to 15 times with the mallet.

   **Note 2:** The measure should be slightly over full, about 3 mm (1/8 in.) above the rim. If there is a great excess of concrete, remove a portion with the scoop. If the measure is under full, add a small quantity. This adjustment may be done only after consolidating the final layer and before striking off the surface of the concrete.

13. Strike off by pressing the strike-off plate flat against the top surface, covering approximately 2/3 of the measure. Withdraw the strike-off plate with a sawing motion to finish the 2/3 originally covered. Cover the original 2/3 again with the plate; finishing the remaining 1/3 with a sawing motion (do not lift the plate; continue the sawing motion until the plate has cleared the surface of the measure). Final finishing may be accomplished with several strokes with the inclined edge of the strike-off plate. The surface should be smooth and free of voids.

14. Clean off all excess concrete from the exterior of the measure including the rim.

15. Determine and record the mass of the measure and the concrete.

16. If the air content of the concrete is to be determined, proceed to Rodding Procedure Step 13 of the FOP for AASHTO T 152.
Procedure - Internal Vibration

1. Perform Steps 1 through 3 of the rodding procedure.

2. Use the scoop to fill the measure approximately 1/2 full with concrete. Evenly distribute the concrete in a circular motion around the inner perimeter of the measure.

3. Insert the vibrator at three different points in each layer. Do not let the vibrator touch the bottom or side of the measure.

   **Note 3:** Remove the vibrator slowly, so that no air pockets are left in the material.

   **Note 4:** Continue vibration only long enough to achieve proper consolidation of the concrete. Over vibration may cause segregation and loss of appreciable quantities of intentionally entrained air.

4. Slightly overfill the measure. Evenly distribute the concrete in a circular motion around the inner perimeter of the measure.

5. Insert the vibrator as in Step 3. Do not let the vibrator touch the side of the measure, but do penetrate the first layer approximately 25 mm (1 in.).

6. Return to Step 13 of the rodding procedure and continue.

Procedure – Self Consolidating Concrete

1. Perform Steps 1 through 3 of the rodding procedure.

2. Use the scoop to slightly overfill the measure. Evenly distribute the concrete in a circular motion around the inner perimeter of the measure.

3. Complete steps 13 thru 16 of the rodding procedure.

Calculations

**Density**

\[ D = \frac{M_m}{V_m} \]

Where:

\[ D \] = density of the concrete mix

\[ M_m \] = mass of concrete in measure

\[ V_m \] = volume of measure (Annex A)

**Yield m³**
\[
Y_{m^3} = \frac{W}{D}
\]

Where:
- \(Y_{m^3}\) = yield (\(m^3\) of the batch of concrete)
- \(W\) = total mass of the batch of concrete

**Yield yd\(^3\)**

\[
Y_{ft^3} = \frac{W}{D} \quad Y_{yd^3} = \frac{Y_{ft^3}}{27 ft^3/yd^3}
\]

Where:
- \(Y_{ft^3}\) = yield (\(ft^3\) of the batch of concrete)
- \(Y_{yd^3}\) = yield (\(yd^3\) of the batch of concrete)
- \(W\) = total mass of the batch of concrete
- \(D\) = density of the concrete mix

**Note 5:** The total mass, \(W\), includes the masses of the cement, water, and aggregates in the concrete.

**Cement Content**

\[
N = \frac{N_t}{Y}
\]

Where:
- \(N\) = actual cementitious material content per \(Y_{m^3}\) or \(Y_{yd^3}\)
- \(N_t\) = mass of cementitious material in the batch
- \(Y\) = \(Y_{m^3}\) or \(Y_{yd^3}\)

**Note 6:** Specifications may require Portland Cement content and supplementary cementitious materials content.

**Water Content**

The mass of water in a batch of concrete is the sum of:
- water added at batch plant
- water added in transit
- water added at jobsite
- free water on coarse aggregate*
- free water on fine aggregate*
- liquid admixtures (if required by the agency)

This information is obtained from concrete batch tickets collected from the driver. Use the Table 2 to convert liquid measures.

*Mass of free water on aggregate

\[
\text{Free Water Mass} = \frac{\text{CA or FC Aggregate}}{1 + \left(\frac{\text{Free Water Percentage}}{100}\right)}
\]

Where:

- Free Water Mass = on coarse or fine aggregate
- FC or CA Aggregate = mass of coarse or fine aggregate
- Free Water Percentage = percent of moisture of coarse or fine aggregate

**Water/Cement Ratio**

\[
\frac{\text{Water Content}}{\text{C}}
\]

Where:

- Water Content = sum mass of water in the batch
- C = sum mass of cementitious materials

**Example**

Mass of concrete in measure (\(M_m\)) 16.290 kg (36.06 lb)

Volume of measure (\(V_m\)) 0.007079 m\(^3\) (0.2494 ft\(^3\))

From batch ticket:

- Yards batched 4 yd\(^3\)
- Cement 950 kg (2094 lb)
- Fly ash 180 kg (397 lb)
- Coarse aggregate 3313 kg (7305 lb)
- Fine aggregate 2339 kg (5156 lb)
- Water added at plant 295 L (78 gal)

**Other**
Water added in transit 0
Water added at jobsite 38 L (10 gal)
Total mass of the batch of concrete (W) 7115 kg (15,686 lb)
Moisture content of coarse aggregate 1.7%
Moisture content of fine aggregate 5.9%

Density

\[ D = \frac{M_m}{V_m} \]

\[ D = \frac{16.920 \text{ kg}}{0.007079 \text{ m}^3} = 2390 \text{ kg/m}^3 \]

\[ D = \frac{36.06 \text{ lb}}{0.2494 \text{ ft}^3} = 144.6 \text{ lb/ft}^3 \]

Given:

\[ M_m = 16.920 \text{ kg (36.06 lb)} \]

\[ V_m = 0.007079 \text{ m}^3 (0.2494 \text{ ft}^3) \text{ (Annex A)} \]

Yield m³

\[ Y_{m^3} = \frac{W}{D} \]

\[ Y_{m^3} = \frac{7115 \text{ kg}}{2390 \text{ kg/m}^3} = 2.98 \text{ m}^3 \]

Given:

Total mass of the batch of concrete (W), kg = 7115 kg
Yield yd$^3$

\[ Y_{ft^3} = \frac{W}{D} \quad Y_{yd^3} = \frac{Y_{ft^3}}{27 ft^3/yd^3} \]

\[ Y_{ft^3} = \frac{15,686 \text{ lb}}{144.6 \text{ lb/ft}^3} = 108.48 \text{ ft}^3 \quad Y_{yd^3} = \frac{108.48 \text{ ft}^3}{27 \text{ ft}^3/yd^3} = 4.02 \text{ yd}^3 \]

Given:

Total mass of the batch of concrete (W), lb = 15,686 lb

Cement Content

\[ N = \frac{N_t}{Y} \]

\[ N = \frac{950 \text{ kg} + 180 \text{ kg}}{2.98 \text{ m}^3} = 379 \text{ kg/m}^3 \quad N = \frac{2094 \text{ lb} + 397 \text{ lb}}{4.02 \text{ yd}^3} = 620 \text{ lb/yd}^3 \]

Given:

N$_t$ (cement) = 950 kg (2094 lb)

N$_t$ (flyash) = 180 kg (397 lb)

Y = $Y_m^3$ or $Y_{yd^3}$

Note 6: Specifications may require Portland Cement content and supplementary cementitious materials content.
Free Water

Free Water Mass = CA or FC Aggregate - \( \frac{CA or FC Aggregate}{1 + (\text{Free Water Percentage}/100)} \)

CA Free Water = 3313 kg - \( \frac{3313 \text{ kg}}{1 + (1.7/100)} \) = 55 kg

CA Free Water = 7305 lb - \( \frac{7305 \text{ lb}}{1 + (1.7/100)} \) = 122 lb

FA Free Water = 2339 kg - \( \frac{2339 \text{ kg}}{1 + (5.9/100)} \) = 130 kg

FA Free Water = 5156 lb - \( \frac{5156 \text{ lb}}{1 + (5.9/100)} \) = 287 lb

Given:

CA aggregate = 3313 kg (7305 lb)

FC aggregate = 2339 kg (5156 lb)

CA moisture content = 1.7%

FC moisture content = 5.9%
**Water Content**

Sum of all water in the mix.

\[
Water\ Content = [(78\ \text{gal} + 10\ \text{gal}) \times 3.785\ \text{kg/gal}] + 55\ \text{kg} + 130\ \text{kg} = 518\ \text{kg}
\]

\[
Water\ Content = [(78\ \text{gal} + 10\ \text{gal}) \times 8.34\ \text{lb/gal}] + 130\ \text{lb} + 287\ \text{lb} = 1151\ \text{lb}
\]

**Given:**

- Water added at plant = 295 L (78 gal)
- Water added at the jobsite = 38 L (10 gal)

**Water/Cement Ratio**

\[
W/C = \frac{518\ \text{kg}}{950\ \text{kg} + 180\ \text{kg}} = 0.458
\]

\[
W/C = \frac{1151\ \text{lb}}{2094\ \text{lb} + 397\ \text{lb}} = 0.462
\]

**Report 0.46**

**Report**

- Results on forms approved by the agency
- Sample ID

- Cementitious material content to 1 kg/m³ (1 lb/yd³)
- Water/Cement ratio to 0.01
ANNEX A

STANDARDIZATION OF MEASURE

Standardization is a critical step to ensure accurate test results when using this apparatus. Failure to perform the standardization procedures as described herein will produce inaccurate or unreliable test results.

Apparatus

- Listed in the FOP for AASHTO T 121
  - Measure
  - Balance or scale
  - Strike-off plate
- Thermometer: Standardized liquid-in-glass, or electronic digital total immersion type, accurate to 0.5°C (1°F)

Procedure

1. Determine the mass of the dry measure and strike-off plate.
2. Fill the measure with water at a temperature between 16°C and 29°C (60°F and 85°F) and cover with the strike-off plate in such a way as to eliminate bubbles and excess water.
3. Wipe the outside of the measure and cover plate dry, being careful not to lose any water from the measure.
4. Determine the mass of the measure, strike-off plate, and water in the measure.
5. Determine the mass of the water in the measure by subtracting the mass in Step 1 from the mass in Step 4.
6. Measure the temperature of the water and determine its density from Table A1, interpolating as necessary.
7. Calculate the volume of the measure, \( V_m \), by dividing the mass of the water in the measure by the density of the water at the measured temperature.
Calculations

\[ V_m = \frac{M}{D} \]

Where:

- \( V_m \) = volume of the mold
- \( M \) = mass of water in the mold
- \( D \) = density of water at the measured temperature

Example

Mass of water in Measure = 7.062 kg (15.53 lb)

Density of water at 23°C (73.4°F) = 997.54 kg/m³ (62.274 lb/ft³)

\[ V_m = \frac{7.062 \text{ kg}}{997.54 \text{ kg/m}^3} = 0.007079 \text{ m}^3 \]
\[ V_m = \frac{15.53 \text{ lb}}{62.274 \text{ lb/ft}^3} = 0.2494 \text{ ft}^3 \]

- Measure ID
- Date Standardized
- Temperature of the water
- Volume, $V_m$, of the measure
Following are guidelines for the use of WAQTC FOP for AASHTO T 152 (Concrete 13-1 (17), published October 2017) by the State of Alaska DOT&PF.

1. An alternate calibration procedure may be used as found in Standard Practice 8.

2. Correction Factors should be checked for each new aggregate source and for sources that have a history of a correction factor in excess of 0.4 percent.

3. If the slump is 1 in or less, consolidate by vibrator. If the slump is above 1 in, consolidate by rodding. Concrete for curb and gutter shall be rodded regardless of slump.
This page intentionally left blank.
AIR CONTENT OF FRESHLY MIXED CONCRETE BY THE PRESSURE METHOD
FOP for AASHTO T 152

Scope
This procedure covers determination of the air content in freshly mixed Portland Cement Concrete containing dense aggregates in accordance with AASHTO T 152-17, Type B meter. It is not for use with lightweight or highly porous aggregates. This procedure includes standardization of the Type B air meter gauge, Annex A.

Warning—Fresh Hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.

Apparatus
- Air meter: Type B, as described in AASHTO T 152
- Balance or scale: Accurate to 0.3 percent of the test load at any point within the range of use (for Method 1 standardization only)
- Tamping rod: 16 mm (5/8 in.) diameter and 400 mm (16 in.) to 600 mm (24 in.) long, having a hemispherical tip the same diameter as the rod. (Hemispherical means “half a sphere”; the tip is rounded like half of a ball.)
- Vibrator: 9000 vibrations per minute, 19 to 38 mm (0.75 to 1.50 in.) in diameter, at least 75 mm (3 in.) longer than the section being vibrated for use with low slump concrete
- Scoop: a receptacle of appropriate size so that each representative increment of the concrete sample can be placed in the container without spillage.
- Container for water: rubber syringe (may also be a squeeze bottle)
- Strike-off bar: Approximately 300 mm x 22 mm x 3 mm (12 in. x 3/4 in. x 1/8 in.)
- Strike-off plate: A flat rectangular metal plate at least 6 mm (1/4 in.) thick or a glass or acrylic plate at least 12 mm (1/2 in.) thick, with a length and width at least 50 mm (2 in.) greater than the diameter of the measure with which it is to be used. The edges of the plate shall be straight and smooth within tolerance of 1.5 mm (1/16 in.).

Note 1: Use either the strike-off bar or strike-off plate; both are not required.
- Mallet: With a rubber or rawhide head having a mass of 0.57 ±0.23 kg (1.25 ±0.5 lb)
Procedure Selection

There are two methods of consolidating the concrete – rodding and vibration. If the slump is greater than 75 mm (3 in.), consolidation is by rodding. When the slump is 25 to 75 mm (1 to 3 in.), internal vibration or rodding can be used to consolidate the sample, but the method used must be that required by the agency in order to obtain consistent, comparable results. For concrete with slumps less than 25 mm (1 in.), consolidate the sample by internal vibration. Do not consolidate self-consolidating concrete (SCC).

Procedure – Rodding

1. Obtain the sample in accordance with the FOP for WAQTC TM 2. If the concrete mixture contains aggregate retained on the 37.5mm (1½ in.) sieve, the aggregate must be removed in accordance with the Wet Sieving portion of the FOP for WAQTC TM 2.

   Note 2: Testing shall begin within five minutes of obtaining the sample.

2. Dampen the inside of the air meter measure and place on a firm level surface.

3. Use the scoop to fill the measure approximately 1/3 full with concrete. Evenly distribute the concrete in a circular motion around the inner perimeter of the measure.

4. Consolidate the layer with 25 strokes of the tamping rod, using the rounded end. Distribute the strokes evenly over the entire cross section of the concrete. Rod throughout its depth without hitting the bottom too hard.

5. Tap around the perimeter of the measure smartly 10 to 15 times with the mallet to close voids and release trapped air.

6. Add the second layer, filling the measure about 2/3 full. Evenly distribute the concrete in a circular motion around the inner perimeter of the measure.

7. Consolidate this layer with 25 strokes of the tamping rod, penetrating about 25 mm (1 in.) into the bottom layer.

8. Tap around the perimeter of the measure smartly 10 to 15 times with the mallet.

9. Add the final layer, slightly overfilling the measure. Evenly distribute the concrete in a circular motion around the inner perimeter of the measure.

10. Consolidate this layer with 25 strokes of the tamping rod, penetrating about 25 mm (1 in.) into the second layer.

11. Tap around the perimeter of the measure smartly 10 to 15 times with the mallet.

   Note 3: The measure should be slightly over full, about 3 mm (1/8 in.) above the rim. If there is a great excess of concrete, remove a portion with the trowel or scoop. If the measure is under full, add a small quantity. This adjustment may be done only after consolidating the final layer and before striking off the surface of the concrete.

12. Strike off the surface of the concrete and finish it smoothly with a sawing action of the strike-off bar or plate, using great care to leave the measure just full. The surface should be smooth and free of voids.

13. Clean the top flange of the measure to ensure a proper seal.

14. Moisten the inside of the cover and check to see that both petcocks are open and the main air valve is closed.
15. Clamp the cover on the measure.
16. Inject water through a petcock on the cover until water emerges from the petcock on the other side.
17. Incline slightly and gently rock the air meter until no air bubbles appear to be coming out of the second petcock. The petcock expelling water should be higher than the petcock where water is being injected. Return the air meter to a level position and verify that water is present in both petcocks.
18. Close the air bleeder valve and pump air into the air chamber until the needle goes past the initial pressure determined for the gauge. Allow a few seconds for the compressed air to cool.
19. Tap the gauge gently with one hand while slowly opening the air bleeder valve until the needle rests on the initial pressure. Close the air bleeder valve.
20. Close both petcocks.
21. Open the main air valve.
22. Tap around the perimeter of the measure smartly with the mallet.
23. With the main air valve open, lightly tap the gauge to settle the needle, and then read the air content to the nearest 0.1 percent.
24. Release or close the main air valve.
25. Open both petcocks to release pressure, remove the concrete, and thoroughly clean the cover and measure with clean water.
26. Open the main air valve to relieve the pressure in the air chamber.

**Procedure - Internal Vibration**

1. Obtain the sample in accordance with the FOP for WAQTC TM 2. If any aggregate 37.5mm (1½ in.) or larger is present, aggregate must be removed in accordance with the Wet Sieving portion of the FOP for WAQTC TM 2.
2. Dampen the inside of the air meter measure and place on a firm level surface.
3. Use the scoop to fill the measure approximately 1/2 full with concrete. Evenly distribute the concrete in a circular motion around the inner perimeter of the measure.
4. Insert the vibrator at three different points. Do not let the vibrator touch the bottom or side of the measure. Remove the vibrator slowly, so that no air pockets are left in the material. Continue vibration only long enough to achieve proper consolidation of the concrete. Over vibration may cause segregation and loss of appreciable quantities of intentionally entrained air.
5. Use the scoop to fill the measure a bit over full. Evenly distribute the concrete in a circular motion around the inner perimeter of the measure.
6. Insert the vibrator as in Step 4. Do not let the vibrator touch the side of the measure, and penetrate the first layer approximately 25 mm (1 in.). Remove the vibrator slowly, so that no air pockets are left in the material. Continue vibration only long enough to achieve proper consolidation of the concrete. Over vibration may cause segregation and loss of appreciable quantities of intentionally entrained air.
7. Return to Step 12 of the rodding procedure and continue.
Procedure – Self Consolidating Concrete

1. Obtain the sample in accordance with the FOP for WAQTC TM 2.
2. Dampen the inside of the air meter measure and place on a firm level surface.
3. Use the scoop to slightly overfill the measure. Evenly distribute the concrete in a circular motion around the inner perimeter of the measure.

Report

- Results on forms approved by the agency
- Sample ID
- Percent of air to the nearest 0.1 percent.
- Some agencies require an aggregate correction factor in order to determine total percent of entrained air.

  Total % entrained air = Gauge reading – aggregate correction factor from mix design

(See AASHTO T 152 for more information.)
Annex A—Standardization of Air Meter Gauge

Standardization is a critical step to ensure accurate test results when using this apparatus. Failure to perform the standardization procedures as described below will produce inaccurate or unreliable test results.

Standardization shall be performed at a minimum of once every three months. Record the date of the standardization, the standardization results, and the name of the technician performing the standardization in the log book kept with each air meter.

There are two methods for standardizing the air meter, mass or volume, both are covered below.

1. Screw the short piece of straight tubing into the threaded petcock hole on the underside of the cover.
2. Determine and record the mass of the dry, empty air meter measure and cover assembly (mass method only).
3. Fill the measure nearly full with water.
4. Clamp the cover on the measure with the tube extending down into the water. Mark the petcock with the tube attached for future reference.
5. Add water through the petcock having the pipe extension below until all air is forced out the other petcock. Rock the meter slightly until all air is expelled through the petcock.
6. Wipe off the air meter measure and cover assembly; determine and record the mass of the filled unit (mass method only).
7. Pump up the air pressure to a little beyond the predetermined initial pressure indicated on the gauge. Wait a few seconds for the compressed air to cool, and then stabilize the gauge hand at the proper initial pressure by pumping up or relieving pressure, as needed.
8. Close both petcocks and immediately open the main air valve exhausting air into the measure. Wait a few seconds until the meter needle stabilizes. The gauge should now read 0 percent. If two or more tests show a consistent variation from 0 percent in the result, change the initial pressure line to compensate for the variation, and use the newly established initial pressure line for subsequent tests.
9. Determine which petcock has the straight tube attached to it. Attach the curved tube to external portion of the same petcock.
10. Pump air into the air chamber. Open the petcock with the curved tube attached to it. Open the main air valve for short periods of time until 5 percent of water by mass or volume has been removed from the air meter. Remember to open both petcocks to release the pressure in the measure and drain the water in the curved tube back into the measure. To determine the mass of the water to be removed, subtract the mass found in Step 1 from the mass found in Step 5. Multiply this value by 0.05. This is the mass of the water that must be removed. To remove 5 percent by volume, remove water until the external standardization vessel is level full.

Note A1: Many air meters are supplied with a standardization vessel(s) of known volume that are used for this purpose. Standardization vessel must be protected from crushing or denting. If an external standardization vessel is used, confirm what percentage volume it represents for the air meter being used. Vessels commonly represent 5 percent volume, but they are for specific size meters. This should be confirmed by mass.

11. Remove the curved tube. Pump up the air pressure to a little beyond the predetermined initial pressure indicated on the gauge. Wait a few seconds for the compressed air to cool, and then
stabilize the gauge hand at the proper initial pressure by pumping up or relieving pressure, as needed.

12. Close both petcocks and immediately open the main air valve exhausting air into the measure. Wait a few seconds until the meter needle is stabilized. The gauge should now read 5.0 ±0.1 percent. If the gauge is outside that range, the meter needs adjustment. The adjustment could involve adjusting the starting point so that the gauge reads 5.0 ±0.1 percent when this standardization is run, or could involve moving the gauge needle to read 5.0 percent. Any adjustment should comply with the manufacturer’s recommendations.

13. When the gauge hand reads correctly at 5.0 percent, additional water may be withdrawn in the same manner to check the results at other values such as 10 percent or 15 percent.

14. If an internal standardization vessel is used, follow steps 1 through 8 to set initial reading.

15. Release pressure from the measure and remove cover. Place the internal standardization vessel into the measure. This will displace 5 percent of the water in the measure. (See AASHTO T 152 for more information on internal standardization vessels.)

16. Place the cover back on the measure and add water through the petcock until all the air has been expelled.

17. Pump up the air pressure chamber to the initial pressure. Wait a few seconds for the compressed air to cool, and then stabilize the gauge hand at the proper initial pressure by pumping up or relieving pressure, as needed.

18. Close both petcocks and immediately open the main air valve exhausting air into the measure. Wait a few seconds until the meter needle stabilizes. The gauge should now read 5 percent.

19. Remove the extension tubing from threaded petcock hole in the underside of the cover before starting the test procedure.

ATM 506  Making and Curing Concrete Test Specimens in the Field

Following are guidelines for the use of WAQTC FOP for AASHTO T 23 (Concrete 14-1 (17), published October 2017) by the State of Alaska DOT&PF.

1. Under “Apparatus” add:
   - Shims
   - Bubble Level

2. When Concrete test specimens are made in conjunction with other testing, (WAQTC FOP for AASHTO T 121 and WAQTC FOP for AASHTO T 152), the same method of consolidation must be used for all tests.

3. When cylinders must be transported, transportation time shall not exceed 8 hours. If this transportation time requirement cannot be met, the transportation time must be approved by the Engineer in writing prior to transporting.

4. Acceptance testing may be done with either 150 mm by 300 mm (6 in by 12 in) cylinders or 100 mm by 200 mm (4 in by 8 in) cylinders.

5. For “Method 1 - Initial cure in a temperature controlled chest-type curing box” between step 1 and step 2 insert:
   - Place the curing box in an area that will not be disturbed by construction activities. Ensure curing box is level, use shims if needed.

6. For “Method 2 - Initial cure by burying in earth or by using a curing box over the cylinder” before step 1 add:
   - Choose a curing location that will not be disturbed by construction activities.
This page intentionally left blank.
METHOD OF MAKING AND CURING CONCRETE TEST SPECIMENS IN THE FIELD FOP FOR AASHTO T 23

Scope
This procedure covers the method for making, initially curing, and transporting concrete test specimens in the field in accordance with AASHTO T 23-17.

Warning—Fresh Hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.

Apparatus and Test Specimens

- Concrete cylinder molds: Conforming to AASHTO M 205 with a length equal to twice the diameter. Standard specimens shall be 150 mm (6 in.) by 300 mm (12 in.) cylinders. Mold diameter must be at least three times the maximum aggregate size unless wet sieving is conducted according to the FOP for WAQTC TM 2. Agency specifications may allow cylinder molds of 100 mm (4 in.) by 200 mm (8 in.) when the nominal maximum aggregate size does not exceed 25 mm (1 in.).

- Beam molds: Rectangular in shape with ends and sides at right angles to each other. Must be sufficiently rigid to resist warpage. Surfaces must be smooth. Molds shall produce length no more than 1.6 mm (1/16 in.) shorter than that required (greater length is allowed). Maximum variation from nominal cross section shall not exceed 3.2 mm (1/8 in.). Ratio of width to depth may not exceed 1:5; the smaller dimension must be at least 3 times the maximum aggregate size. Standard beam molds shall result in specimens having width and depth of not less than 150 mm (6 in.). Agency specifications may allow beam molds of 100 mm (4 in.) by 100 mm (4 in.) when the nominal maximum aggregate size does not exceed 38 mm (1.5 in.). Specimens shall be cast and hardened with the long axes horizontal.

- Standard tamping rod: 16 mm (5/8 in.) in diameter and 400 mm (16 in.) to 600 mm (24 in.) long, having a hemispherical tip of the same diameter as the rod for preparing 150 mm (6 in.) x 300 mm (12 in.) cylinders.

- Small tamping rod: 10 mm (3/8 in.) diameter and 305 mm (12 in.) to 600 mm (24 in.) long, having a hemispherical tip of the same diameter as the rod for preparing 100 mm (4 in.) x 200 mm (8 in.) cylinders.

- Vibrator: At least 9000 vibrations per minute, with a diameter no more than ¼ the diameter or width of the mold and at least 75 mm (3 in.) longer than the section being vibrated for use with low slump concrete.

- Scoop: a receptacle of appropriate size so that each representative increment of the concrete sample can be placed in the container without spillage.

- Trowel or float

- Mallet: With a rubber or rawhide head having a mass of 0.57 ±0.23 kg (1.25 ±0.5 lb.).

- Rigid base plates and cover plates: may be metal, glass, or plywood.

- Initial curing facilities: Temperature-controlled curing box or enclosure capable of maintaining the required range of 16 to 27°C (60 to 80°F) during the entire initial curing period (for concrete with
compressive strength of 40 Mpa (6000 psi) or more, the temperature shall be 20 to 26°C (68 to 78°F). As an alternative, sand or earth for initial cylinder protection may be used provided that the required temperature range is maintained and the specimens are not damaged.

- Thermometer: Capable of registering both maximum and minimum temperatures during the initial cure.

**Procedure – Making Specimens – General**

1. Obtain the sample according to the FOP for WAQTC TM 2.
2. Wet Sieving per the FOP for WAQTC TM 2 is required for 150 mm (6 in.) diameter specimens containing aggregate with a nominal maximum size greater than 50 mm (2 in.); screen the sample over the 50 mm (2 in.) sieve.
3. Remix the sample after transporting to testing location.
4. Begin making specimens within 15 minutes of obtaining the sample.
5. Set molds upright on a level, rigid base in a location free from vibration and relatively close to where they will be stored.
6. Fill molds in the required number of layers, attempting to slightly overfill the mold on the final layer. Add or remove concrete prior to completion of consolidation to avoid a deficiency or excess of concrete.
7. There are two methods of consolidating the concrete – rodding and internal vibration. If the slump is greater than 25 mm (1 in.), consolidation may be by rodding or vibration. When the slump is 25 mm (1 in.) or less, consolidate the sample by internal vibration. Agency specifications may dictate when rodding or vibration will be used.

**Procedure – Making Cylinders – Self Consolidating Concrete**

1. Use the scoop to slightly overfill the mold. Evenly distribute the concrete in a circular motion around the inner perimeter of the mold.
2. Strike off the surface of the molds with tamping rod, straightedge, float, or trowel.
3. Immediately begin initial curing.

**Procedure – Making Cylinders – Rodding**

1. For the standard 150 mm (6 in.) by 300 mm (12 in.) specimen, fill each mold in three approximately equal layers, moving the scoop or trowel around the perimeter of the mold to evenly distribute the concrete. For the 100 mm (4 in.) by 200 mm (8 in.) specimen, fill the mold in two layers. When filling the final layer, slightly overfill the mold.
2. Consolidate each layer with 25 strokes of the appropriate tamping rod, using the rounded end. Distribute strokes evenly over the cross section of the concrete. Rod the first layer throughout its depth without forcibly hitting the bottom. For subsequent layers, rod the layer throughout its depth penetrating approximately 25 mm (1 in.) into the underlying layer.
3. After rodding each layer, tap the sides of each mold 10 to 15 times with the mallet (reusable steel molds) or lightly with the open hand (single-use light-gauge molds).

4. Strike off the surface of the molds with tamping rod, straightedge, float, or trowel.

5. Immediately begin initial curing.

**Procedure – Making Cylinders – Internal Vibration**

1. Fill the mold in two layers.

2. Insert the vibrator at the required number of different points for each layer (two points for 150 mm (6 in.) diameter cylinders; one point for 100 mm (4 in.) diameter cylinders). When vibrating the bottom layer, do not let the vibrator touch the bottom or sides of the mold. When vibrating the top layer, the vibrator shall penetrate into the underlying layer approximately 25 mm (1 in.)

3. Remove the vibrator slowly, so that no large air pockets are left in the material.

   **Note 1:** Continue vibration only long enough to achieve proper consolidation of the concrete. Over vibration may cause segregation and loss of appreciable quantities of intentionally entrained air.

4. After vibrating each layer, tap the sides of each mold 10 to 15 times with the mallet (reusable steel molds) or lightly with the open hand (single-use light-gauge molds).

5. Strike off the surface of the molds with tamping rod, straightedge, float, or trowel.

6. Immediately begin initial curing.

**Procedure – Making Flexural Beams – Rodding**

1. Fill the mold in two approximately equal layers with the second layer slightly overfilling the mold.

2. Consolidate each layer with the tamping rod once for every 1300 mm² (2 in²) using the rounded end. Rod each layer throughout its depth, taking care to not forcibly strike the bottom of the mold when compacting the first layer. Rod the second layer throughout its depth, penetrating approximately 25 mm (1 in.) into the lower layer.

3. After rodding each layer, strike the mold 10 to 15 times with the mallet and spade along the sides and end using a trowel.

4. Strike off the surface of the molds with tamping rod, straightedge, float, or trowel.

5. Immediately begin initial curing.

**Procedure – Making Flexural Beams – Vibration**

1. Fill the mold to overflowing in one layer.

2. Consolidate the concrete by inserting the vibrator vertically along the centerline at intervals not exceeding 150 mm (6 in.). Take care to not over-vibrate, and withdraw the vibrator slowly to avoid large voids. Do not contact the bottom or sides of the mold with the vibrator.

3. After vibrating, strike the mold 10 to 15 times with the mallet.

4. Strike off the surface of the molds with tamping rod, straightedge, float, or trowel.

5. Immediately begin initial curing.
Procedure – Initial Curing

- When moving cylinder specimens made with single use molds support the bottom of the mold with trowel, hand, or other device.
- For initial curing of cylinders, there are two methods, use of which depends on the agency. In both methods, the curing place must be firm, within ¼ in. of a level surface, and free from vibrations or other disturbances.
- Maintain initial curing temperature of 16 to 27°C (60 to 80°F) or 20 to 26°C (68 to 78°F) for concrete with strength of 40 Mpa (6000 psi) or more.
- Prevent loss of moisture.

Method 1 – Initial cure in a temperature controlled chest-type curing box

1. Finish the cylinder using the tamping rod, straightedge, float, or trowel. The finished surface shall be flat with no projections or depressions greater than 3.2 mm (1/8 in.).
2. Place the mold in the curing box. When lifting light-gauge molds be careful to avoid distortion (support the bottom, avoid squeezing the sides).
3. Place the lid on the mold to prevent moisture loss.
4. Mark the necessary identification data on the cylinder mold and lid.

Method 2 – Initial cure by burying in earth or by using a curing box over the cylinder

Note 2: This procedure may not be the preferred method of initial curing due to problems in maintaining the required range of temperature.

1. Move the cylinder with excess concrete to the initial curing location.
2. Mark the necessary identification data on the cylinder mold and lid.
3. Place the cylinder on level sand or earth, or on a board, and pile sand or earth around the cylinder to within 50 mm (2 in.) of the top.
4. Finish the cylinder using the tamping rod, straightedge, float, or trowel. Use a sawing motion across the top of the mold. The finished surface shall be flat with no projections or depressions greater than 3.2 mm (1/8 in.).
5. If required by the agency, place a cover plate on top of the cylinder and leave it in place for the duration of the curing period, or place the lid on the mold to prevent moisture loss.

Procedure – Transporting Specimens

- Initially cure the specimens for 24 to 48 hours. Transport specimens to the laboratory for final cure. Specimen identity will be noted along with the date and time the specimen was made and the maximum and minimum temperatures registered during the initial cure.
- Protect specimens from jarring, extreme changes in temperature, freezing, or moisture loss during transport.
• Secure cylinders so that the axis is vertical.
• Do not exceed 4 hours transportation time.

**Final Curing**

• Upon receiving cylinders at the laboratory, remove the cylinder from the mold and apply the appropriate identification.

• For all specimens (cylinders or beams), final curing must be started within 30 minutes of mold removal. Temperature shall be maintained at 23° ±2°C (73 ±3°F). Free moisture must be present on the surfaces of the specimens during the entire curing period. Curing may be accomplished in a moist room or water tank conforming to AASHTO M 201.

• For cylinders, during the final 3 hours prior to testing the temperature requirement may be waived, but free moisture must be maintained on specimen surfaces at all times until tested.

• Final curing of beams must include immersion in lime-saturated water for at least 20 hours before testing.
Report

- On forms approved by the agency.
- Pertinent placement information for identification of project, element(s) represented, etc.
- Sample ID
- Date and time molded.
- Test ages.
- Slump, air content, and density.
- Temperature (concrete, initial cure max. and min., and ambient).
- Method of initial curing.
- Other information as required by agency, such as: concrete supplier, truck number, invoice number, water added, etc.
Following are guidelines for the use of FOP for AASHTO R 64 by the State of Alaska DOT&PF.

1. Three specimens shall be cast for each test age required.

2. Applicable sections of AASHTO T 106 shall be followed for final curing, testing compressive strength and reporting test results.
FIELD SAMPLING AND FABRICATION OF 50 MM (2 IN.) CUBE SPECIMENS USING GROUT (NON-SHRINK) AND OR MORTAR
WAQTC FOP FOR AASHTO R 64

1. Scope

This method covers field sampling and fabrication and initial curing of 50 mm (2 in.) cube specimens of non-shrink grout and/or mortar materials.

The values stated in either SI or inch-pound units shall be regarded separately as standard. The inch-pound units are shown in brackets. The values stated might not be exact equivalents; therefore, each system must be used independently of the other.

Note 1: Unit weight was the previous terminology used to describe the property determined by this test method, which is mass per unit volume.

The text of this test method references notes and footnotes that provide explanatory information. These notes and footnotes (excluding those in tables) shall not be considered as requirements of this test method.

Warning—This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

Warning—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.

2. Referenced Documents

AASHTO / ASTM

- C 1107 Standard Specification for Packaged Dry, Hydraulic-Cement Grout (Non-shrink)
- T 106 / C 109 Test method for Compressive Strength of Hydraulic Cement Mortars (Using 50 mm or 2 in. Cube Specimens.)

3. Definitions

Fluid mix: Material fluid enough that little or no indentation will be left in the surface after puddling.

Plastic mix: Material viscous enough that an indentation will be left in the surface of the grout after tamping.

4. Apparatus

- Specimen Molds including cover plate(s): The 2 in. (50 mm) cube specimen molds shall be tight fitting and made of brass or other suitable material. This material shall not be susceptible to attack by the cement mortar. The molds shall have not more than three (3) cube compartments and shall be separable into not more than two (2) parts. The parts of the molds, when assembled, shall be positively held together. The cover plate(s) working surface shall be plane and shall be positively attached to the side walls of the mold. The interior faces of the molds shall conform to the tolerances of Table 1.

</tbody>
</table>

*Measured at points slightly removed from the intersection. Measured separately for each compartment between all the interior faces and the adjacent face and between interior faces and top and bottom planes of the mold.*

- Tamper: A non-absorptive, nonabrasive, non-brittle material such as a hard rubber compound having a Shore A durometer hardness of 80 ± 10. The tamper shall have a cross section of about 1/2 in. × 1 in. (13 mm × 25 mm) and a length of 5 in. to 6 in. (125 mm to 150 mm). The tamping face shall be flat and at right angles to the length of the tamper.

- Trowel: Steel bladed 100 to 150 mm (4 in to 6 in) in length, with straight edges.

- Water tight container: a 150 mm × 300 mm (6 in × 12 in) concrete cylinder mold with lid

- Other Equipment: Rubber gloves, scoop, clamps to secure the cover plate, light release oil for oiling the molds, small brush or lint-free cloth for applying and removing excess release oil, burlap or wrapping cloth capable of retaining moisture.

5. **Sampling**

1. Samples shall be obtained in accordance with WAQTC TM 2 when the batch equals or exceeds 1 m³ (1 yd³). When the batch is less than 1 m³ (1 yd³) sample from the batch after discharge. If remixing is required sample after remixing. Begin molding the specimens within an elapsed time of not more than 2 1/2 minutes from completion of the mixing.

   *Note 2:* Use this test for grouts with 100% passing the 9.5 mm (3/8 inch) sieve.

2. Obtain a representative sample of the mix. Samples shall be a minimum size of 2000 g (4 lb) for each set of three (3) cubes to be fabricated.

6. **Procedure**

1. Assemble both portions of the mold and the bottom cover plate. All joints shall be water tight. If not water tight, seal the surfaces where the halves of the mold join by applying a coating of light cup grease (non water soluble). The amount should be sufficient to extrude slightly when the halves are tightened together. Repeat this process for attaching the mold to the bottom cover plate. Remove any excess grease. Apply a thin coating of release agent to the interior faces of the mold and the bottom cover plate. Wipe the mold faces and base plate as necessary to remove any excess release agent and to achieve a thin, even coating on the interior surfaces. Adequate coating is that which is just sufficient to allow a distinct fingerprint to remain following light finger pressure.
2. Place a layer of grout about 25 mm (1 in) (approximately one-half of the depth of the mold) in all of the cube compartments. Consolidated according to the consistency (plastic or fluid) of the mix.
   a. For plastic mixes, tamp the lift in four rounds of 8 tamps for a total of 32 tamps with the rubber tamper in 10 seconds. See Figure 1 for tamping sequence of each round. Rounds 1 and 3; and rounds 2 and 4 shall be the same.
   b. For fluid mixes, puddle the lift 5 times with a gloved finger. See Figure 2 for puddling sequence.
3. Place the second lift in each of the cube compartments, slightly over-filling each compartment. Consolidate the material in the same fashion as the first lift with the additional requirement that during consolidation of the second lift any grout forced out onto the top of the mold after each round will be pushed back onto the compartment by means of the tamper and/or gloved fingers before the next consolidation round. When consolidation of the grout is completed, material should extend slightly above the top of the mold. Push any grout forced out onto the top of the mold after the last round back onto the compartment with the trowel.
4. Smooth off the cubes by drawing the flat side of the trowel (with the leading edge slightly raised) once across the top of each cube at right angles to the length of the mold. Then, for the purpose of leveling the mortar and making the mortar that protrudes above the top of the mold of more uniform thickness, draw the flat trailing edge of the trowel (with leading edge slightly raised) once lightly along the length of the mold. Cut off the mortar to a plane surface flush with the top of the mold by drawing the straight edge of the trowel (held nearly perpendicular to the mold) with a sawing motion over the length of the mold. The material shall be flush with the top of the mold.
5. Immediately secure the top cover plate to the cube mold.
6. **Initial Curing** - Place the molds in a secure location away from vibration and as close as possible to the structure for initial curing. Cover with wet burlap, towels, or rags, seal it in a plastic sack in a level location out of direct sunlight, and record the time. These samples shall remain undisturbed and protected from freezing or overheating for a period of 24 to 28 hours.
7. At the end of the initial curing period as required by the agency either;
   a. Place the sealed plastic sack into a water tight container. Transport the cube samples immediately to the location of final curing. During transport, the cube samples shall be protected from jarring, freezing, and moisture loss.
   b. Disassemble the mold and carefully remove the cube samples. Using a permanent marker, identify the cube samples. Handling the cube samples very carefully, wrap them in wet burlap or wet towels and place them into a water tight container. Transport the cube samples immediately to the location of final curing. During transport, the cube samples shall be protected from jarring, freezing, and moisture loss.

Final curing shall consist of immersing the cube samples in a lime-saturated water storage tank at a temperature of 23.0 ± 2.0°C (73.5 ± 3.5°F). They are to remain in the storage tank until time of test. (Curing cube samples of material other than hydraulic cement shall be in conformance with the manufacturer’s recommendations.) The storage tank shall be made of non-corroding materials.

ATM 508 Slump Flow of Self-Consolidating Concrete

1. Scope

This procedure provides instructions for determining the slump flow of self-consolidating concrete (SCC) in accordance with ASTM C1611/C1611M.

Warning—Fresh Hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue under prolonged exposure.

2. Apparatus

- Cone: The SCC shall be placed in a slump cone mold conforming to the applicable requirements of ATM 503.
- Sample receptacle: Pan or wheel barrow that is water tight, has a non-absorbent surface, and large enough to retain a volume of concrete sufficient to perform all necessary testing and to fill all necessary sample specimen containers.
- Base plate: Flat, rigid, non-absorbent moistened surface having a minimum diameter of 915 mm (36 in.).
- Scoop or Pouring Vessel: A water tight container having a volume such that concrete is not spilled during placement in the mold.
- Strike-off bar: A flat straight steel bar, at least 3mm x 20 mm x 300 mm (1/8 x3/4 x 12 inches), or plastic bar twice as thick as the steel bar.
- Tape measure or ruler with at least 5 mm or 1/4 in. graduations.

3. Procedure

1. Obtain the sample in accordance with ATM 501.
   
   Note 1: Testing shall begin within five minutes of obtaining the sample.

2. Remix sample using shovel or scoop.

3. Dampen the inside of the cone and the base plate.

4. Place cone in center of leveled base plate, in the inverted position, as shown in Figure 1.
5. Fill the cone in one lift with a representative sample of concrete. Allow the concrete to flow into the cone without dropping the concrete from more than 5 inches above the inverted cone. Fill the cone slightly over full.

*Note 2:* Do not rod concrete. Do not tap or vibrate the cone. If concrete has been rodded, tapped, or vibrated discard sample, the test is invalid.

6. Strike off the top surface of concrete level with the top of the cone with a screeding motion of the strike-off bar.

7. Remove any spilled or struck off concrete from around the base of the cone so it does not inhibit the flow of the SCC mix.

8. Raise the cone vertically with a smooth fluid motion, without twisting or jerking, in 3 ± 1 seconds.

*Note 3:* Complete the entire test from the start of filling through removal of the cone without interruption within an elapsed time of 2 ½ minutes.

9. Wait for the concrete to stop flowing and then measure the largest diameter ($d_1$) of the resulting spread of concrete. When a halo is observed in the resulting circular spread of concrete, it shall be included as part of the diameter of the concrete. Measure a second diameter ($d_2$) of the circular spread of concrete at an angle approximately perpendicular to the first measured diameter ($d_1$). Measure the diameters to the nearest 5mm [1/4 in].

### 4. Calculation

Calculate the Slump Flow as follows:

$$\text{Slump flow} = \frac{(d_1 + d_2)}{2}$$

Where:

- $d_1 =$ the largest diameter of the circular spread of the concrete, and
- $d_2 =$ the circular spread of the concrete at an angle perpendicular to $d_1$. 

---

**Figure 1**

[Diagram of a conical flow test setup]
1. If the measurement of the two diameters differs by more than 50 mm [2 in.], the test is invalid and shall be repeated.

2. Record the average of the two diameters to the nearest 10 mm [1/2 in.].

5. **Report**
   - On forms approved by the Department
   - Date
   - Time
   - Location, source and sampling method
   - Quantity represented
   - Report the slump flow to the nearest 10 mm [1/2 in.].
   - Report visual segregation index (VSI) based on photos below; matching nearest photo.

---

**Figure 2: Examples for visual inspection of slump flow.**

![Image](image_url)

**VSI 0: Stable mix, no evidence of segregation or bleeding.**
VSI 1: Stable mix, only slight bleeding.

VSI 2: Unstable mix, visible separation around edges (halo) and bleeding.
VSI 3: Unstable mix, visible halo around edges, segregation in middle, excessive bleeding.

ATM 509 Fabricating Test Specimens with Self-Consolidating Concrete

1. Scope

This procedure provides instructions for fabricating test specimens in the laboratory or field using a sample of freshly mixed self-consolidating concrete (SCC). This practice is applicable to SCC with a nominal maximum aggregate size of 25 mm [1 in.] and a slump flow of 500 mm [20 in.] or greater. If the slump flow is less than 500 mm [20 in.] follow the fabrication procedures described in the standard for which the test specimen is required.

Warning—Fresh Hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue under prolonged exposure.

2. Apparatus

- Cylinder Molds: Molds for casting SCC specimens shall conform to the requirements of ATM 506.
- Beam Molds: Molds for casting SCC specimens shall conform to requirements of ATM 506.
- Scoop or Pouring Vessel: A water tight container having a volume such that concrete is not spilled during placement in the mold.
- Strike-off bar, trowel or float.

3. Procedure

1. Obtain the sample in accordance with ATM 501.
2. After transporting sample to testing location remix sample using shovel or scoop.
3. Begin making specimens within 15 minutes of obtaining the sample.
4. Fill the mold with a representative sample of concrete. Slightly overfill by tilting the scoop and pouring the sample around the perimeter of the mold to allow the SCC to flow into the mold and to ensure an even distribution of concrete.
   
   Note 1: Do not rod the concrete or tap the sides of the specimen mold.
   
   Note 2: If slump flow is below 500 mm [20 in.] follow standard procedures for fabricating test specimens found in ATM 506.
5. After filling, strike off the mold with either the strike off bar, trowel or float. Cover specimens and immediately place on a flat, level surface for initial curing in accordance with ATM 506.
6. After initial curing, follow transporting and final curing procedures listed in ATM 506.

4. Report

- On forms approved by the Department
- Date and Time
- Location, source and sampling method
- Quantity represented
This page intentionally left blank.
1. Scope
This method describes Volumetric Mix Design procedures for determining the optimum proportions for Portland Cement Concrete both with and without supplemental cementitious materials. Both ACI 211 and Packing Density proportioning procedures are included in this method.

2. Significance
Concrete proportions, properties and performance depend on the aggregate that forms most of the matrix of this composite material. Many proportioning methods have been used historically to produce concrete. This method includes both ACI 211 and Packing Density proportioning procedures. Combined Aggregate gradations that plot near the maximum density line on a gradation curve typically require less cementitious material and produce concretes with lower shrinkage than concretes that use open-graded aggregates such as those specified in AASHTO M 43 and AASHTO M 6.

3. Apparatus
- Ovens and hot plates thermostatically controlled to maintain the various required temperatures within ± 3°C (5°F).
- Fresh Concrete Testing equipment for Slump, Air, Unit Weight, and Temperature, AASHTO T 119, T 152, T 121, and ASTM C1064/C respectively.
- Water bath with temperature control sensitive to ± 0.2°C (0.5°F) at 23°C (73.4°F) per AASHTO T 85.
- Balance or scale: Capacity sufficient for the principal sample mass, readable to 0.1 g or 0.1 percent of the total sample mass and meeting the requirements of AASHTO M 231.
- Sieve shaker meeting the requirements of WAQTC FOP for AASHTO T 27/T 11.
- Specimen molds, either 4x8” or 6x12” with lid that conform to ASTM C470.
- Compression testing machine meeting the requirements of ASTM C39 and referenced documents.
- Surface Resistivity testing apparatus meeting the requirements of AASHTO TP 95.
- Shrinkage testing apparatus meeting the requirements of ASTM C157.

4. Aggregates
Aggregate proportions may be selected by either ACI 211 or Packing Density procedures. Aggregate properties important to concrete mixes shall be determined as follows:

4.1. Gradations shall be performed in accordance with AASHTO T 11 and T 27

4.1.1. AASHTO M 6 and M 43 gradations are appropriate for the ACI 211 proportioning method. Fineness modulus will also need to be calculated for the fine aggregate when using the ACI proportioning method.

4.1.2. When three or more aggregates are available then combined gradations, conforming to Table 1, may be advantageous and shall be calculated from proportion and gradation of each component aggregate. Various Packing Density proportioning procedures may be used with combined gradations that are within Table 1 limits.
4.2. Duplicate apparent, bulk SSD, and bulk specific gravities and absorption values of each fine & coarse aggregate shall be determined in accordance with AASHTO T 84 and T 85 respectively. The average of the duplicate test values shall be used in the mix design.

4.3. Sodium Sulfate Soundness testing shall be done on both the coarse (retained on #4 sieve) and fine (passing #4 sieve) aggregates or on the coarse and fine fractions of the combined aggregate in accordance with AASHTO T 104.

5. Cementitious Materials

Cementitious materials acceptable for concrete shall include; Portland Cement, Class C and F Fly Ash, Natural Pozzolans, Ground, Granulated Blast Furnace Slag (GGBF), Silica Fume, and Meta-Kaolin.

6. Admixtures

Admixture materials acceptable for concrete shall include: water-reducers, surfactants, viscosity modifiers, air-entrainment agents, crack reducers, shrinkage reducers, accelerators, retarders, surface sealers, hardeners and finishing aides.

7. Fibers

Fiber materials are acceptable for reinforcement, shrinkage and crack control in concrete and shall include; steel, stainless steel, synthetic, and alkali-resistant cellulose fibers.
8. Internal Curing

Internal curing may be used to increase tensile and compressive strength, reduce internal stresses and reduce shrinkage in concrete. Internal curing materials include; expanded shale, clay or slate fine aggregates, alkali-resistant cellulose, super-absorbent polymers, and naturally occurring aggregates of volcanic origin meeting ASTM C1761.

9. Determination of Concrete Proportions by ACI 211.1

1. Select slump appropriate for the type of construction
2. Select maximum size of aggregate so concrete can be placed without excessive segregation or voids.
3. Estimate mixing water and entrained-air content for exposure class, selected slump and maximum aggregate size.
4. Select water-cementitious materials ratio needed to provide required durability and compressive strength.
5. Calculate the cementitious materials content based on steps 3-4 above.
6. Estimate coarse aggregate content using ACI 211.1 Table 6.3.6 - Volume of coarse aggregate per volume of concrete.
7. Calculate fine aggregate content. At the end of step 6 all ingredients of the concrete have been estimated except the fine aggregate. The fine aggregate content is calculated by difference.

10. Determination of Concrete Proportions by Packing Density

1. Select maximum size of aggregate so concrete can be placed without excessive segregation or voids.
2. Blend available aggregates to produce the highest packing density as evaluated by 0.45 power chart.
3. Determine the volume of voids in the combined aggregate.
4. Estimate the amount of excess paste required to provide desired workability.
5. Calculate volume of paste required to fill the aggregate voids.
6. Calculate volume of aggregates.
7. Calculate weights of each aggregate.
8. Select w/c ratio based on compressive strength requirements
9. Calculate cement content.
10. Calculate water content.
11. Determine required entrained air content for exposure conditions and maximum aggregate size.

11. Trial Batches

1. A minimum of three trial batches for no-air concrete and six trial batches for air-entrained will be required to establish w/c vs. strength and air vs. strength relationships. For establishing strength vs. w/c ratio three batches are to be made at three different cement contents and three different w/c ratios. The constant paste method works well for these batches. (For example use 6.0 sack mix at 0.50 w/c, 6.5 sack at 0.45 w/c and 7.0 sack at 0.40 w/c)
2. When designing air-entrained concrete begin with no-air trial batches to establish w/c vs. strength relationship.
3. Make 3 air-entrained batches at the highest strength limits (low w/c ratio) of the data. Try to produce batches with air contents at optimum and at more than 1.5% above and below optimum to produce data covering the typically specified range of acceptable air contents. This will provide sufficient data to produce a valid Strength vs. Entrained-Air relationship. Provide graphs of w/c vs. compressive strength and (for air-entrained concrete) % entrained-air vs. compressive strength with each mix design.

(Note: The graphs of w/c vs. compressive strength and entrained-air vs. compressive strength provide design and construction personnel with valuable strength information for acceptance/rejection decisions should concrete arrive at the job site that is outside w/c or entrained-air limits. The graphs also provide a basis for reductions of cement content when more than 15 consecutive strength tests provide data justifying a lower over-design value)

4. Prepare first trial batch and check for workability, under-sanded or over-sanded proportions

5. If first trial batch mix parameters are satisfactory then proceed with two additional trial batches with same volume of paste but higher and lower cement contents and lower and higher w/c ratios respectively such that high w/c mix falls below minimum compressive strength and lower w/c ratio falls just below the workability range with the maximum recommended dose of water-reducing and/or workability enhancing admixtures. If the initial trial batch is not near the middle of the w/c range, then prepare a fourth batch near the optimum w/c ratio. For air-entrained concrete you will need at least three additional trial batches, as noted above, to produce the % entrained-air vs. compressive strength curve.

12. Determination of Fresh Concrete Properties

1. Test for temperature, slump or slump flow (if SCC mix), wet unit weight, and entrained-air content

13. Preparing Concrete Test Specimens for High Performance Concrete

1. Cast 15 each 4x8” or 10 each 6x12” test cylinders for compressive strength testing of each trial batch. For Type I/II cement break 3each 4x8” or 2 each 6x12” specimens at 3, 7, 14, 28 days and hold three specimens for possible break at a later age. (Note: High fly ash content concretes may continue to gain significant strength for several years. Additional test specimens should be cast for these mixes as compressive strength at 56 days, 90 days, 1 year and 2 years may be significant.) For Concrete made with Type III cement break 3each 4x8” or 2 each 6x12” specimens at 1, 2, 3, 7 days and hold three specimens for possible break at a later age.

2. When flexural strength criteria applies cast one set of three beams for each trial batch per AASHTO T 97 (ASTM C78). Measure and record all data for each set of specimens and include it in mix design report.

3. When maximum shrinkage criteria applies cast one set of shrinkage specimens for each trial batch per ASTM C157. Measure and record all data for each set of specimens and include it in mix design report.

14. Curing of Specimens

1. Cure compressive and flexural specimens in fog room or water bath as specified in ASTM C511

15. Determination of Hardened Concrete Properties

1. Remove test specimens from molds 24 ± 4 hours after casting. Determine hardened unit weight of all specimens by soaking test specimens in 23°C water for 15 minutes then weighing in water followed by weighing in air at SSD.

2. When concrete is subject to exterior environmental conditions, determine the Resistivity of each specimen by AASHTO TP 95 no more than 24 hours prior to compression testing. Record specimen age at testing and resistivity for each specimen. Average each set of readings and include data in mix design reports.

3. When flexural strength is required cast three beams in accordance with ASTM C78, test at the required age and include data in mix design report.
4. When maximum shrinkage criteria applies test one set of restrained shrinkage specimens for each trial batch per ASTM C1581, measure and record required shrinkage data and include data in mix design report.

16. Graphing, Determination of Optimum w/c Ratio and Analysis of Test Results

1. Graph the 28 day (7 day for Type III cement) compressive strength vs. w/c ratio for the no-air trial batches. Graph the no-air compressive strength on the y-axis vs. w/c ratio on the x-axis and include a linear best-fit line through the data points.

2. For concrete that is not air-entrained determine the required overdesign and calculate f’cr. Follow the required f’cr value horizontally to the intercept with the strength vs. w/c ratio line and from this point drop a vertical line down to the w/c ratio line and record the value. This is the maximum w/c ratio that will provide the required f’cr.

3. Graph the 28 day (7 day for Type III cement) compressive strength vs. air content for the three batches made at the lowest w/c ratio of the no-air batches. Provide the best-fit, linear equation for the data such that strength may be calculated as a function of air content. Draw a vertical line from the optimum air content on the x-axis up to where it intersects the air vs. strength line. From that point draw a horizontal line across to the strength (y) axis. Record this compressive strength value and plot this point on the no-air strength vs. w/c ratio graph.

4. On the no-air strength vs. w/c ratio graph containing the optimum air point compressive strength draw a line through this point parallel to the no-air strength line.

5. Draw a horizontal line through the required over-design strength (f’cr) for the air-entrained concrete that intersects its strength vs. w/c ratio line. At this intersection drop a vertical line down to the w/c (x) axis. Record this w/c ratio as the maximum allowed for the air-entrained mix design. This point (w/c, f’cr) will provide the critical proportions for the submitted mix design and for a proof batch by the owner agency. (DOT&PF typically requires materials for a proof batch to verify concrete mixes made from material without a previous history.)

6. The graphical data will also provide the basis for reductions or increases in cement content as strength data is accumulated on a new mix design. (When 15-30 consecutive strength tests justify reduction in the initial over-design strength (f’cr) according to ACI 301 Sections 4.2.3.2 through 4.2.3.6c then the concrete producer or supplier may submit a request to lower the cement content along with the consecutive strength test data to the engineer for consideration of the requested reduction. Conversely, if strengths below f’cr or if there is high variability in strength tests, then the engineer may request an increase in the cement content).

17. Report

The report shall include the following:

- Project identification, Source/Supplier of mix and name of the general contractor when mix design is specific for a single project.

- Aggregate source(s), quality identification(s), target gradation, blend ratio of individual stockpiles, individual and blended aggregate absorption values, apparent, bulk SSD, and bulk specific gravities for Coarse and Fine Aggregate Fractions. Other properties that may be specified include; Unit Weight of dry-rodded coarse aggregate, fineness modulus of the blended fine aggregate, percent flat and elongated; sodium sulfate soundness of coarse and fine aggregate fractions, or aggregate-silica reactivity (ASR).

- Gradation(s), with graphical representation on 0.45 power graph of combined aggregate gradation for Packing Density mixes or AASHTO M 6 and M 43gradations for ACI 211.1 mixes. Include Lower
Specification Limit (LSL) and Upper Specification Limit (USL) data with both combined and ACI gradations.

- An orderly presentation of all trial batch data including; type(s) and source certificate with chemical oxide analysis for all cementitious materials, trial batch proportions, complete test cylinder data with unit weight of all cylinders determined immediately after initial curing period and removal from molds, surface resistivity (when required) of test cylinders, with nominal cylinder size indicated, just before compressive testing, compressive strength and average compressive strength at each age. Include graphs of Compressive strength vs. w/c Ratio and Compressive strength vs. Air content (for air-entrained mixes). Plot trial batch data points on graph(s) along with best-fit linear trend line. For trial batch nearest to selected mix design proportions plot Strength vs. Age points and the best-fit smoothed curve through the data points. Plot theoretical unit weight vs. Air Content for selected mix design proportions from 1% Air to 10% Air and include the linear equation corresponding to plotted line in the form y = mx + b.

- Identification and address of the laboratory that performed the mix design, mix design identification number and the signed seal of the professional engineer who reviewed and approved the mix design.
Appendix A

Definitions

1. **Absolute Volume** – Solid volume of a material exclusive of all particle void spaces. This is calculated by the following formula:

   Absolute Volume (Cubic Feet) = Weight of Material / (Specific Gravity x 62.4)

   For example: A sack of Portland cement occupies a bulk volume of approximately 1 cubic foot. The absolute volume is about 0.478 cubic foot.

   \[
   94 \text{ lbs} / (3.15 \times 62.4 \text{ lbs/ft}^3) = 0.478 \text{ cubic foot}
   \]

2. **Specific Gravity** – A ratio expression of the weight in air of an absolute volume of material to the weight of an equal volume of water.

3. **Fineness Modulus (FM)** – An empirical factor obtained by adding the total percentages of a sample of fine aggregate retained on each of the following sieves, that sum divided by 100.

   Sieve numbers 4, 8, 16, 30, 50, 100

   For example:

<table>
<thead>
<tr>
<th>Sieve Size</th>
<th>% Passing</th>
<th>% Retained</th>
</tr>
</thead>
<tbody>
<tr>
<td>#4</td>
<td>98</td>
<td>2</td>
</tr>
<tr>
<td>#8</td>
<td>90</td>
<td>10</td>
</tr>
<tr>
<td>#16</td>
<td>68</td>
<td>32</td>
</tr>
<tr>
<td>#30</td>
<td>42</td>
<td>58</td>
</tr>
<tr>
<td>#50</td>
<td>20</td>
<td>80</td>
</tr>
<tr>
<td>#100</td>
<td>6</td>
<td>94</td>
</tr>
</tbody>
</table>

   Sum = 276

   Fineness Modulus calculation: 276 / 100 = 2.76
Appendix B

Example Calculations for ACI 211.1 Method

1. Select an appropriate value of slump from ACI Table 6.3.1
   (Use 3 inch slump for this example)

2. Choose a nominal maximum size of coarse aggregate based on guidelines in ACI section 6.3.2
   (Use ¾ inch for this example. Include gradation conforming to AASHTO M 43 size 67 for ¼ to #4)

3. Estimate mixing water and air content per cubic yard of concrete based on ACI section 6.3.3 and Table 6.3.3
   (Use 305 pounds of water for exterior concrete with air-entrainment, and select 6% air for severe exposure)

4. Select w/c ratio to give desired strength per ACI 6.3.4 and Table 6.3.4a
   (Assume 4000 psi required compressive strength and select 0.48 for the w/c ratio)

5. Calculate the cement content in pounds per cubic yard of concrete, ACI 6.3.5, as follows:
   (305 pounds / 0.48 = 635 pounds cement)

6. Estimate coarse aggregate content, ACI 6.3.6 and Table 6.3.6
   a. In this example use FM = 2.76 for fine aggregate with ¾ inch coarse aggregate to get a coarse aggregate bulk volume fraction of 0.62
   b. Use ASTM C29 to determine Bulk Unit Weight of coarse aggregate. Assume 102 pounds/ft³ for this example.
   c. For one cubic yard batch proportions coarse aggregate = 0.62 (27 ft³/yd³) (102 lbs/ft³)
      Weight of coarse aggregate = 1707 pounds/yd³

7. At the completion of step 6 all ingredient amounts are known except for the fine aggregate which is determined by difference, ACI 6.3.7, using the volumetric method. Use specific gravity of 2.68 for coarse aggregate (CA) and 2.71 for fine aggregate (FA). Include FA gradation meeting AASHTO M 6.
   a. Volume of water: = 305 lbs / 62.4 lbs/ft³ = 4.89 ft³
   b. Solid Volume of cement: = 635 lbs / (3.15 x 62.4 lbs/ft³) = 3.23 ft³
   c. Solid Volume of CA = 1707 lbs / (2.68 x 62.4 lbs/ft³) = 10.21 ft³
   d. Volume of air = 0.06 x 27.0 ft³ = 1.62 ft³
   e. Subtotal of all ingredients except fine aggregate = 19.95 ft³
   f. Solid Volume of FA = 27 – 19.95 = 7.05 ft³
   g. Required weight of dry FA =7.05 ft³ x 2.71 x 62.4 lbs/ft³ = 1192 lbs.

8. Follow ACI 211.1 Sections 7.2.8 to 7.3.10 for adjustments for aggregate moisture, slump, workability and mix harshness.
Appendix C

Example Calculations for Packing Density Method

1. Create maximum density aggregate blend from available sources.

2. Use ASTM C29 to determine Bulk Unit Weight of combined aggregate and then calculate the volume of voids in one cubic yard.
   
   Packing density = 0.7223
   
   Voids content = 1 – 0.7223 = 0.2777

3. Estimate the amount of excess paste required to provide desired workability.
   
   Excess paste for 3” slump = 10%

4. Calculate the total amount of paste required.
   
   Paste content = 0.2777 + 0.10 x 0.2777 = 0.3054

5. Calculate Volume of aggregates.
   
   Volume of aggregates = 1 – 0.3054 = 0.6945

6. Calculate weights of each aggregate assuming a three aggregate blend of 42% CA, 18% IA, and 40% FA with specific gravities of 2.712, 2.736, and 2.593 respectively.
   
   Solid Volumes of Aggregates = 0.42 / 2.712 + 0.18 / 2.736 + 0.40 / 2.593 = 0.3749
   
   CA = (0.6945 / 0.3749) x 0.42 x 62.4 lbs/ft³ x 27 ft³/yd³ = 1311 lbs/yd³
   
   IA = (0.6945 / 0.3749) x 0.18 x 62.4 lbs/ft³ x 27 ft³/yd³ = 562 lbs/yd³
   
   FA = (0.6945 / 0.3749) x 0.40 x 62.4 lbs/ft³ x 27 ft³/yd³ = 1248 lbs/yd³

7. Select w/c ratio to give desired strength and calculate cement content.
   
   (Assume 4000 psi required compressive strength and select 0.48 for the w/c ratio)
   
   w/c = 0.48; w = 0.48c
   
   Total paste = c + w = c/3.15 + 0.48c/1 =0.7975c
   
   Cement content = 0.3054/0.7975 x 62.4 lbs/ft³ x 27 ft³/yd³ = 645 lbs/yd³

8. Calculate water content.
   
   Water content = 0.48 x 645 lbs/yd³ = 310 lbs/yd³

9. Make adjustments for aggregate moisture, slump, workability and mix harshness and entrained air.

</table>

By proportion (weight by volume) supplied by the Contractor.

Each separate component will be mixed separately and then mixed together to form the aggregate.

The coordinating agency may sample each component aggregate prior to introduction to the weigh hopper or any other device determined by the Engineer.

Sample maximum size for concrete aggregate is defined as the smallest standard size opening through which the entire amount of the aggregate.

All proportions are by weight.

**Note:** The table continues with similar entries for other sizes and components.

Project No:  
Quantity Rep.:  
Date Completed:  
Lab Number:

Sample Preparation:
Use table below to determine sample size. If more than 15% retained on 1-1/2" sieve, test the portion separately. 
from the smaller material. Multiple fractions may be used. 
率ke the reduced sample over a #4 sieve and wash
all dust from the sample.

Procedure:
1. Dry to constant mass at 100 ± 2°C. Cool at room temperature for 1-3 hrs, or until sample can be handled
   comfortably.
2. Completely submerge sample in water at room temperature and soak for 15-19 hrs. (ASTM 24 ± 4 hrs)
   Note: AASHTO allows initial drying to be eliminated if aggregate will be used in concrete mixtures in its
   naturally wet condition. The 15 hour soaking period may be eliminated if surfaces of the sample have been
   kept continuously wet until the test was begun.
3. Take wire basket and handling scoop in preparation for submerging sample. Ensure water bath is at overflow
   level.
4. Record temperature of water bath, verifying it is 23 ± 1°F (23 ± 2°C for ASTM).
5. Remove sample from water and roll in absorbent towel until no visible water is seen. Place in handling scoop.
6. Immediately record mass of sample in air, at SSD condition, to minimize loss from evaporation. (E)
7. Place sample in wire basket attached to scale in water bath. Shake the basket to release trapped air bubbles.
8. Record mass of sample while submerged. (Be sure to return handling scoop to top of scale or loss will be off)
9. Dry to constant mass at 100 ± 5°C. Cool at room temperature 1-3 hrs until sample can be handled comfortably.
10. Record oven dry mass. (A)

Note: Report Sp-G to nearest 0.001 (AASHTO C516 ASTM)

Page 1 of 1
Duplicate Fine Aggregate Specific Gravities & Absorption

**AASHTO T 84 (ASTM C128)** Duplicate Relative Density, (Sp G) and Absorption of Fine Aggregate

**Client:** Project: 
**Client Address:** Material/Use: 
**Submitted by:** 
**Sampled from:** Field Number: 
**Sampled by:** Date Sampled: 
**Test Location:** Received by: 
**Date Received:** 
**Depth:** Testing Tech: 
**Project No:** 
**Quantity Rep:** 
**Date Completed:** 
**Lab Number:** 

**Sample Preparation:**
1. Obtain 2 each, 1 kg samples in accordance with T 2 (D 75) and T 248 (C 702) for duplicate tests.
2. Dry to constant mass then add a minimum of 6% moisture after cooling. Allow samples to stand 15-19 hrs. (24 ± 4 hrs for ASTM)
   a. Initial drying is optional if aggregates will be used for concrete mixtures and are still in their moist states.
3. Decant excess water with care to avoid loss of fines. Spread sample on nonabsorbent surface, and position sample in gently moving warm air. On short table use fan, heat lamp, and fumes to speed up evaporation during the drying process.
4. Press cone mold to a nonabsorbent surface and fill to overflowing, keeping additional material above top of mold by holding it with cupped fingers of hand holding the mold.
   a. Keep constant pressure on mold, use tender, and allow 25 lbs to aggregate. Letting temper fall under its own weight from approximately 2.2 in. (56mm) above the top surface of the aggregate.
5. Clear the area around the mold and remove the cone, being careful not to agitate the material.
   a. Slight damping of the material indicates SSD; retention of the molded shape indicates surface moisture.
   b. Stamping after striking the table indicates the cone test should be run again immediately.
6. Repeat steps 4-5 until material reaches SSD. Fill the pyrometer immediately after reading SSD.

**Note:** Angular aggregate, samples containing large proportions of fines may require additional methods.

**Procedure:** (Bold letters indicate data entry points)
1. Partially fill (1/3), the calibrated pyrometer with water, insert funnel with tube, and close.
2. Introduce 500 ± 10 grams of selected SSD material into flask. Record the mass of material to 0.1 g (C).
3. Fill flask to approximate 75% capacity with additional water, manually agitate 15-20 min to remove visible air.
   a. Manually agitate by rolling on rubber pad or between your hands.

**Note:** A small amount of propyl alcohol may be used to disperse the foam.
4. Adjust the temperature of the pyrometer and contents to 33.0 ± 1.0°C (23.0 ± 2.0°C for ASTM) (D).
5. Bring the mass level to the calibrated mark. The bottom of meniscus should rest on the calibrated line.
6. Record mass of pyrometer, sample, and water to 0.1 g (C).
7. Record and report the current absorption of water from the current calibration sheet (D).
8. Determine the mass of the sample and dry the sample again (within 0.1 g) using 110°C oven (A).
9. Use a waste bottle to wash all the fines from the pyrometer.
   a. If use a waste bottle to wash all the fines from the pyrometer.
   b. Determine the mass of the sample only after it has cooled 1.9% ± 0.5 hrs.

**Note:** Report Sp G. Results to 0.001 (AASHTO 0.01) (ASTM)

**Sample Preparation:**
Obtain sample 125-200% of quantity required to fill measure. Dry to constant mass at 110 ± 3°C.

**Method A: Filling:**
(For nominal maximum size 1 1/2" or less)
1. Record weight of measure to 0.1 lb.
2. Fill measure 1/3 full and level surface with fingers. Red level 25 times with a 3/8" hemispherical tipped rod.

**Avoid Halving Bottom of Measure:**
3. Fill measure 2/3 full, level, and red 25 times. Avoid penetrating the first layer.
4. Fill measure to overflowing and red again. Avoid penetrating the previous layer.
5. Level aggregate using fingers or straight edge so projections above measure balance surface voids.
6. Record weight of full measure to 0.1 lb.

**Method B: Raking:**
(For nominal maximum size 1 1/2" to 3")
1. Record weight of measure to 0.1 lb.
2. Fill measure 1/3 full and level surface with fingers. Placing measure on a solid base, compact by raking opposite sides alternately about 2" and dropping each side 25 times for a total of 50 blows per layer.
3. Fill measure 2/3 full, level, and compact as above.
4. Fill measure to overflowing and compact as above.
5. Level aggregate using fingers or straight edge so projections above measure balance surface voids.
6. Record weight of full measure to 0.1 lb.

**Method C: Shoveling:**
(Calculates Bulk Density - use only if specified)
1. Record weight of measure to 0.1 lb.
2. Fill measure to overflowing with shovel or scoop, discharging from no more than 2" above measure.
3. Avoid segregation of material.
4. Level aggregate using fingers or straight edge so projections above measure balance surface voids.
5. Record weight of full measure to 0.1 lb.

**Bulk Density SSD:**
For bulk density SSD, use the same procedure but calculate using Mixed Formula below.
*Note: Absorption and Sp3 data must be determined using C127 or C123 (fine or coarse Sp3 test)*

Alaska Test Methods Manual 530-15 Effective July 15, 2018
Constant paste volume calculations:

Blue font indicates data entry points; red font indicates a calculation; no data entry in these cells.

1. Start with three w/c ratios 0.03 apart and three cement contents about 1/2 of cement content.
2. For example, w/c = 0.30, 0.45, 0.60 and cement = 6.0, 6.5, 7.0 sack respectively (see below).
3. Go to Data tab in Excel, select What-If Analysis and then Goal Seek while on Total Paste volume cell for 6 sack mix.
4. Set the Goal Seek value to the 6.5 Sack Total Paste Volume of 7.515 ft³ by changing cement value for 6 sack mix.
5. Repeat steps 3 and 4 for the 7 sack batch.
6. Use these three equal paste volumes for preparing strength vs. w/c ratio trial batches to give equivalent workability.

Note: To maintain consistent slump gradually increase dosage of water-reducing admixture while moving to higher cement contents, as the paste gets thicker. Constant slump is desirable for establishing air-entraining agent dosage. Air-entrainment agents are more effective at higher slumps.
